StarOffice™ 5.2

Installation with Response Files

Copyrights and Trademarks

Contents

What is a Response File Installation?

To install a single-user installation you need a valid StarOffice installation set and a StarOffice Setup program. After starting the Setup, you can select various parameters for the installation. For example, you can define which StarOffice Module you want to install.

When installing StarOffice in a network, it needs to be installed or adapted to manage a large number of users, and therefore, installation or configuration by the user or administrator at each workstation is not always the best solution.

For this reason, you, as administrator now have the possibility to automate a central installation, reparation, configuration or deinstallation of StarOffice by using response files. The response file takes over control of the StarOffice Setup program. You can, for example, enter the following information for the StarOffice network installation:

■ Which option should be run: installation, repair, configuration, deinstallation?

■ Which modules are to be installed or deinstalled?

■ For which user/user group should the actions be executed?

At the same time you can define different StarOffice sets and assign these to specific user groups by means of parameters. Similarly you can also define further information, rules or restrictions in Basic scripts and run them during 'StartofSetup', 'Installation' and 'EndofSetup'.

Information about the basic structure and the individual components of a StarOffice Setup response file is listed below. Explanations are also contained showing which Basic commands can be used together with a response file installation. Finally you will be shown the actual methodology by means of a practical example of a response file.

How Do I Install StarOffice with Response Files?

The process followed during a StarOffice remote installation when a response file is used is outlined below:

- Preparing the response file installation

- Creating a response file

- Testing a response file

- Installing StarOffice using a response file

Preparing the Response File Installation

You need to have the following to install StarOffice using response files:

- A valid StarOffice installation set

- Access to the client computer

- The functioning response file

You can create a response file with any editor program.

Creating a Response File

To create a response file:

1. Define which actions are to be run for which user group.

2. Define the rules for running the actions.

3. Define whether you want to allow user feedback when running the actions.

4. Write the response file.

5. Test the response file.

6. Run the response file.

The individual features of working with response files are shown at the end of this booklet in the form of a detailed practical example.

Testing the Response File

Proceed as follows to test a response file:

1. Create a new directory on a network drive.

2. Alter the path details in your response file to match those of this network path.

3. Run the response file from a shell.

4. Check the results of the response file setup in the specified drive.

The return codes produced by the response file can be shown in a message box by entering the `–debug` setup command line parameter. This allows you to see if the response file functions as required.

Install StarOffice Using the Response File

To install StarOffice by using response files:

1. Define in the response file which StarOffice modules are to be installed.

2. Define the installation path.

3. Run the response file.

4. Check the installation, if necessary.

Response File Structure and Sections

This section contains a detailed description of the response file structure needed for the StarOffice Setup, the components used and how they function.

Response File Structure

Section Environment

`[Environment]`

The Environment section describes all of the entries needed when installing with a response file. These entries are normally carried out by the user in the StarOffice Setup or are transferred using parameters. The following keys have been defined for this purpose:

- `InstallationMode`
- `InstallationType`
- `DestinationPath`
- `StartProcedure`
- `EndProcedure`

Section Module_Specify

`[Module_Specify]`

Use this section to compose individual StarOffice module sets and assign them to an installation or deinstallation procedure. You are able to define any combination of the

modules found in the setup script. The modules can be accessed by using either the module name or a module ID.

> Use the –sdump setup command lines parameter to create a setup script file. Also see the setup command lines parameter.

- `'ModulSetName'`
- `InstallModuleSet`
- `DeInstallModuleSet`
- `InstallProcedure`
- `DeInstallProcedure`

Section Procedures

In the Procedures section you can implement basic functions which can be assigned to different positions in the response file, for example, to the 'StarofSetup' or 'EndofSetup' intervals. These functions are independent and, therefore, cannot call each other.

Section Java

Use this section to determine if an existing Java installation is to be included.

Section Explanation

Section Environment

Installation Mode

Values

INSTALL_NORMAL	Installs a local StarOffice standalone version
INSTALL_NETWORK	Installs a StarOffice network version

INSTALL_WORKSTATION	Installs a workstation version from an existing network installation
DEINSTALL	Deinstalls an existing StarOffice version
REPAIR	Repairs a StarOffice version
REINSTALL	Reinstalls a StarOffice version

Default -

The InstallationMode sets the general context under which the response files are run. The INSTALL_NORMAL, INSTALL_NETWORK and INSTALL_WORKSTATION modes in the source medium should be used for initial installations. These three modes also orient   themselves to the **InstallationType** while running**.** The 'INSTALL_WORKSTATION' mode can only be used with the setup found on a network installation.

The 'DEINSTALL', 'REPAIR' and 'REINSTALL' modes can only be used on installed versions. 'DEINSTALL' and 'REPAIR' do not need any further specifications and will be executed immediately. 'REINSTALL' evaluates the [MODULE_SPECIFY] section to determine which actions are to be carried out.

InstallationType

Values

STANDARD	Installs the module selection, defined as the default in the setup script
SPECIFY	Installs the module selection, defined in the [MODULE_SPECIFY] section
MINIMUM	Installs the module selection, defined in setup script as minimal
WORKSTATION	Copies only a small network installation onto the client

Default: STANDARD

The installation type is only valid in the 'INSTALL_*' modes. If the Setup is under the 'WORKSTATION' context, 'STANDARD' installs a complete executable network

version locally on the client, the 'WORKSTATION' type, on the other hand, only installs a small network installation in this mode.

DestinationPath

Values

d:\office5x
<firstfree>\office5x
<home>\office5x

Default: <firstfree> + directory name of DefaultPath from the setup script

You can enter the target path for an installation in absolute terms or relative to an identifier which the Setup replaces. '<firstfree>' will be replaced by the first drive letter found that has enough disk space to store the specified installation type (WIN/WNT). '<home>'will be replaced with the home directory (UNIX).

StartProcedure

Value

ProcedureName

Default: None

The 'StartProcedure' is run before all actions, including those procedures defined with BEFORE_INST in the setup script. The procedure must be implemented in the [PROCEDURES] section.

EndProcedure

Value

ProcedureName

Default: None

The 'EndProcedure' is run after all actions have taken place, including those procedures defined with AFTER_INST in the setup script. The procedure must be implemented in the [PROCEDURES] section.

Section Module_Specify

'ModulSetName' =

Values

ModuleName1, ModuleName2, ...

Default: None

This section is used to define a logical set of modules, which is then accessed through its name at different positions in the response file or via the SetupBASIC. Enter the module names as listed in the setup script after a self-defined name. The module names need to be written in a line and separated by commas. By using the Select-ModuleSet and DeSelectModuleSet functions you can access these module sets with SetupBASIC.

InstallModuleSet

Value

```
ModuleSetName
```

Default: None

Define the module set in the InstallModuleSet which is to be installed when a specific installation type refers to this section and the response file setup has been set in an installation context (e.g. INSTALL_NORMAL, REINSTALL).

DeInstallModuleSet

Value

```
ModuleSetName
```

Default: None

DeInstallModuleSet is used to define the module set to be deinstalled when a specific installation type or mode refer to this section and the response file setup has been set in a deinstallation context (e.g. DEINSTALL, REINSTALL).

InstallProcedure

Value

```
ProcedureName
```

Default: None

InstallProcedure is the name of the procedure that decides which modules are to be installed when an installation type or mode refer to this section. You can access the

module sets by using SetupBASIC. The procedure has to be implemented in the [Procedures] section. If a InstallModuleSet is defined along with InstallProcedure in this section, the procedure will always be run.

DeInstallProcedure

Value

```
DeInstallProcedure
```

Default: None

DeInstallProcedure denotes the procedure that decides which modules are to be deinstalled when an installation type or mode refer to this section. You can access the module sets by using SetupBASIC. The procedure has to be implemented in the [Procedures] section. If you define an additional DeInstallModuleSet in the DeInstall-Procedure in this section, the procedure will always be executed.

Section Procedures

The Procedures section is used to implement the Basic functions to be assigned to different positions in the response file. The functions are independent and cannot call each other.

Example:

```
Sub ProcedureName
        Code ...
EndSub

Sub NextProcedureName
        Code ...
EndSub
```

Section Java

This section defines if an existing Java installation is to be supported.

```
[Java]
JavaSupport=
```

Values

none	not supported
preinstalled_or_none	supports Java, if installed
newinstall	installs Java

If the 'newinstall' switch is being used, you have to manually operate the Java installation dialog.

Setup Command Line Parameter

You can run StarOffice Setup under different command line parameters:

- `[-sdump [-d:<destpath>]]`
- `[-r:<response_file> [-debug]]`

Running StarOffice Setup with Parameters

To run StarOffice Setup with one of the parameters:

1. Start StarOffice Setup from a shell.

2. Enter the required parameter: Example**:**

   `C:\office52\setup.exe -Parameter`

-sdump

SDUMP (ScriptDump)

A Setup started with the SDUMP parameter creates a 'script.htm' HTML file which contains the module hierarchy of the current script. IMPORTANT: This file is written in the currently selected directory if you start the Setup from a CD. If you want to create the file in another directory, you can also enter the '-D:path' (DestinationPath) parameter. This HTML file helps you to define your own ModuleSets when writing response files.

-debug

This parameter sets the Setup to a Debug mode. If an error occurs while running a response file, the corresponding ExitCode and an error description will be displayed in an Error Box before quitting the program. This function is helpful when testing your own response file.

Script.Htm

An example of the HTML file 'script.htm' created with the –sdump setup parameter is found below . You can address each of the topics about the contents of a module set either by name or module ID in the response file.

Basic Setup

In the [Procedures] section you can use Basic to create procedures which are then called up at different intervals when the response file is running. Several functions are described below and these can be used in your response files to directly address the StarOffice Setup.

DirEntry. Function

Syntax

String DirEntry (Path 1 As String, Path 2 As String, ...)

Return

The DirEntry function joins several path components together and converts the results to the current system convention. The result will appear as a string.

Example

```
Sub Test
Dim strAbsPath As String
strAbsPath = DirEntry( GetSetupEnv.DestPath, "help", "01" )

MsgBox strAbsPathEnd Sub
```

System	Result
W16, W95, W2000, WNT	D:\office52\help\01
Unix	/home/Ur/ok/office52/help/01
Macintosh	Hard disk:office52:help:01

Hide/Show Setup. Function

Syntax

void HideSetup ( )

void ShowSetup ( )

Return

The HideSetup function is used to hide the Setup application window when running the response file setup. The ShowSetup function displays the Setup application window tracks and gives feedback about the progress of the installation. The running of the response file setup cannot be influenced by the user as neither of these functions send or receive parameters.

Example

```
Sub Test
HideSetup
MsgBox "gone!"
ShowSetup
MsgBox "and back again!"
End Sub
```

Error Return Codes in the Response File Mode

If Setup confronts an error while working through the response file, it terminates and relays an error code to the initiating program (shell). If you enter the '_debug parameter when starting the setup, the return code will be shown as text in an error box before setup terminates. The following error messages are defined:

Abort	Exit Code	Error Message
Yes	1	resource file cannot be found
Yes	2	response file cannot be found
Yes	3	illegal installation mode
Yes	4	illegal installation type
Yes	5	script version outdated
Yes	6	wrong command line parameter
Yes	7	setup script file cannot be found
Yes	8	script error
Yes	9	INSTALL_INFO flag is missing
Yes	10	ui procedure cannot be found
Yes	11	no modules accessible
Yes	12	update installation cannot be found
Yes	13	no updates for Try&Buy versions
Yes	14	installation file cannot be found
Yes	15	WORKSTATION type only available on a network installation

Abort	Exit Code	Error Message
Yes	16	`error while reading PROCEDURE section`
Yes	17	`version already installed`
Yes	18	`<firstfree> wrong system`
Yes	19	`<home> wrong system`
Yes	20	`not enough space on the destination drive`
Yes	21	`invalid destination path`
Yes	22	`module cannot be found`
Yes	23	`installed version required for this type`
Yes	24	`Install procedure cannot be found`
Yes	25	`installmoduleset cannot be found`
Yes	26	`De-install procedure cannot be found`
Yes	27	`De-install module set cannot be found`
Yes	28	`wrong or invalid license key`
Yes	29	`Invalid license`

Abort	Exit Code	Error Message
No	-	`xterm cannot be found`
No	-	`could not start xterm`
No	-	`start xterm return error code`
No	-	`an error occurred while copying a file`
No	-	`an error occurred while unpacking a file`
No	-	`an error occurred while creating a directory`

Example

The options for installing a response file StarOffice are introduced in the following examples. Each section found in the example contains a short description of the defined specifications.

Section Environment

This section is used to define the framework of the setup to be controlled by the response files.

```
[Environment]
InstallationMode = INSTALL_NORMAL
InstallationType =  SPECIFY
DestinationPath = d:\office52.resp
StartProcedure = MyStartProc
EndProcedure = MyEndProc
```

Comments	
InstallationMode = INSTALL_NORMAL	Installs a StarOffice stand alone version
InstallationType = SPECIFY	Installs the modules defined in the [Module_Specify] section
DestinationPath = d:\office52.resp	Provides an explicit destination path.
StartProcedure = MyStartProc	Defines MyStartProc as the procedure to be run before the Setup start.

Comments	
EndProcedure = MyEndProc	Defines MyEndProc as the procedure to be run after the Setup has been run.

Module Section Specification

Define module sets in this section. You can also directly communicate with or install the defined module sets, or refer to one of the defined Install Procedures in the procedures section.

```
[Module_Specify]
MySet_Writer_Draw = StarOffice Writer 5.2, StarOffice Draw 5.2
MySet_Schedule = StarOffice Schedule 5.2

InstallModuleSet = MySet_Writer_Draw
InstallProcedure = MySelectProc
```

Comments	
MySet_Writer_Draw = StarOffice Writer 5.2, StarOffice Draw 5.2	Determines the StarOffice Writer5.2 and StarOffice Draw5.2 modules as components of the MySet_Writer_Draw set.
MySet_Schedule = StarOffice Schedule 5.2	Defines the StarOffice Schedule5.2 as component of the MySetSchedule set.
InstallModuleSet = MySet_Writer_Draw	Installs all modules which are defined in MySet_Writer_Draw.
InstallProcedure = MySelectProc	Runs the MySelectProc installation procedure.

Section Procedures

Define the procedures to be run at various intervals during the Setup.

```
[Procedures]

Sub MyStartProc
      SetUserFirstName ( "Tom" )
      SetUserLastName ( "Meyer" )
      SetUserID ( "tm" )
      SetUserEMail ( "tm@newcompany.com" )
      SetUserStreet ( "111 Main Street" )
      SetUserZip ( "52365" )
      SetUserCity ( "Springfield" )
      SetUserCompanyname ( "NewCompany" )
      ShowSetup
      MsgBox "Start"
End Sub
```

Comments	
Sub MyStartProc	Begins the MyStartProc procedure
SetUserFirstName ("Tom") SetUserLastName ("Meyer") SetUserID ("TM") SetUserEMail ("tm@newcompany.com")	Determines the user parameters for the StarOffice Installation. These parameters can be used to influence the running time by utilizing environment variables.
ShowSetup	Shows the application window while running the Setup response file.
MsgBox "Start"	Shows a text box with the 'Start' text.
End Sub	End of MyStartProc procedure

```
Sub MyEndProc
      HideSetup
      MsgBox "End"
      DefuseRestart(True)
End Sub
```

Comments	
Sub MyEndProc	Start of the MyEndProc procedure
HideSetup	Hides the StarOffice Setup. application window
MsgBox "End"	Shows the 'End' text in a text box.
DefuseRestart(True)	Prevents the system rebooting after installation
End Sub	End of the MyEndProc procedure

```
Sub MySelectProc
      SelectModuleSet ( "MySet_Schedule" )
rem   DeSelectModuleSet ( "MySet_Schedule" )

      EnvVar = Environ( "vcsid" )
      If EnvVar = "OK"
      Then
            SelectModuleByName ( "StarOffice Chart 5.2" )
      rem DeSelectModuleByName ( "StarOffice Chart 5.2" )
      Endif

      SelectModuleByID ( "gid_Module_Prg_Image" )
rem   DeSelectModuleByID ( "gid_Module_Prg_Image" )
End Sub
```

Comments	
Sub MySelectProc	Begins the MySelectProc procedure.
SelectModuleSet ("MySet_Schedule")	Selects the Module, which is determined a MySet_Schedule component.
Rem DeSelectModuleSet ("MySet_Schedule")	If the Module is deselected, the MySet_Schedule component will be determined

Comments	
EnvVar = Environ("vcsid")	Defines the EnvVar variable and assigns an environment variable as value
If EnvVar = "HE"	Requests the EnvVar with the 'HE' value.
Then SelectModuleByName ("StarOffice Chart 5.2")	Selects further module – StarOffice Chart5.2 - with the module name.
Rem DeSelectModuleByName("StarOffice Chart 5.2")	Deselects the corresponding module with the module name.
Endif	Ends the If loop.
SelectModuleByID ("gid_Module_Prg_Image")	Selects a Module on the basis of its Module ID.
Rem DeSelectModuleByID ("gid_Module_Prg_Image")	Deselects the corresponding module by its module ID
End Sub	Ends the MySelectProc procedure

```
[Java]

JavaSupport = preinstalled_or_none
```

Comments	
JavaSupport = preinstalled_or_none	Java will be supported if a version has already been installed on the system.

Customer Support

If you have any questions regarding support visit our interactive Knowledge Database at:

http://www.sun.com/staroffice/support

We hope you enjoy using StarOffice.
